List of Abbreviations and Acronyms

BOD	biochemical oxygen demand
CCR	California Code of Regulations
CERCLA	Comprehensive Environmental Response Compensation and Liability Act
COC	constituent of concern
CVRWQCB	Central Valley Regional Water Quality Control Board
DMSO	dimethyl sulfoxide
DO	dissolved oxygen
DSWP	sewage percolation pond influent sampling location
EC	electrical conductivity or specific conductance
est	estimated (concentration)
ESWP	sampling location within sewage evaporation pond
HDPE	high-density polyethylene
HMX	octahydro-1, 3, 5, 7-tetranitro-1, 3, 5, 7-tetrazocine (also cyclo-tetramethylene-tetrinitramine)
HPLC	high-performance liquid chromatography
ISWP	sewage pond influent sampling location
LCRS	leachate collection and removal system
LCS	laboratory control sample
LLNL	Lawrence Livermore National Laboratory
m	meters
MDL	method detection limit
MPN	most probable number (of bacteria)
MRP	Monitoring and Reporting Program
MS	matrix spike
MSD	matrix spike duplicate
NA	not applicable
NAFL	not available from laboratory
ND	not detected
NL	no limit

List of Abbreviations and Acronyms (concluded)

NR	analysis not required by permit
NS	not sampled
PCE	tetrachloroethene (tetrachloroethylene, perchloroethylene)
PETN	pentaerythritol tetranitrate
QA	quality assurance
Qal	Quaternary Age alluvium
QC	quality control
RDX	hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (also cyclo-1, 3, 5-trimethylene 2, 4, 6-trinitramine)
RL	reporting limit
SL	statistical test limit
STLC	soluble threshold limit concentration
SVOC	semivolatile organic compound
TATB	2, 4, 6-trinitro-1, 3, 5-benzenetriamine
TCE	trichloroethene (trichloroethylene)
TIC	tentatively identified compound
Tnbs ₁	Tertiary Age, Neroly Formation Lower Blue Sandstone (the regional aquifer)
Tnbs ₂	Tertiary Age, Neroly Formation Upper Blue Sandstone
Tnsc ₁	Tertiary Age, Neroly Formation Lower Siltstone/Claystone
TNT	2, 4, 6-trinitrotoluene (also 2-methyl-1, 3, 5-trinitrobenzene)
VOC	volatile organic compound
WDR	Waste Discharge Requirements (Permit)

Executive Summary

This report contains the elements required by Waste Discharge Requirements (WDR) 96-248 (Permit) for Site 300 for the combined 2004 fourth quarter and annual report. This is the ninth annual report prepared under this Permit. Compliance monitoring networks discussed in the report include:

- Process wastewater discharged into the Class II surface water impoundments (surface impoundment) (**Section 2.2**)
- Leak detection monitoring (including leachate collection and removal system monitoring, and ground water monitoring) for the surface impoundments (**Section 2.3**)
- Wastewater monitoring for the sewage evaporation and percolation ponds (**Section 3.2**)
- Ground water monitoring for the sewage evaporation and percolation ponds (**Section 3.3**)
- Observations at the percolation pits (**Section 4.0**).

The annual report elements are incorporated into this annual/fourth quarter report. Brief narrative summaries of each compliance network lead each section. These narrative summaries discuss compliance and significant incidents that occurred during 2004. Annual summaries of monitoring data are presented in graphical and tabular form in **Appendices A, B, C, and D**. Methods used to determine statistical test limits (SLs) for ground water constituents of concern (COCs) are summarized in **Appendix E**. Fourth quarter quality assurance and quality control (QA/QC) data are summarized in **Appendix F**.

All discharges into the surface impoundments were in compliance with the Permit during 2004.

The following damage to the surface impoundment's high-density polyethylene (HDPE) liner was reported during 2004. The event was reported to Susan Timm of the Central Valley Regional Water Quality Control Board (CVRWQCB) in a phone call on October 14, 2004:

- On October 13, a split in the HDPE liner of the upper surface impoundment was discovered. The split was approximately 6 to 8 inches long and more than three feet above the water line. Several other weak places, or striations, in the liner were noted at the same time. During an inspection on October 25, the damaged areas were observed by Susan Timm of the CVRWQCB. Repairs to all of those locations were completed on November 30, 2004.

LLNL does not expect this occurrence to adversely impact either surface or ground water at Site 300 since the cracks are located above the freeboard line and are unlikely to have contacted wastewater contained in the surface impoundment.

No liquids were discovered in the leachate collection and removal systems (LCRS) during weekly monitoring.

Required ground water monitoring parameters for the surface impoundments were below the specified SLs throughout 2004, except as identified in **Table 1**.

Table 1. COC concentrations exceeding their SLs in 2004.

COC exceeding SL (confirmed by retest)	Down gradient Wells		
	W-817-02	W-817-03	W-817-04
Ammonia	Did not exceed SL	4 th quarter ^a (1/27/2005) ^b	Did not exceed SL
Bicarbonate alkalinity	Did not exceed SL	Did not exceed SL	1 st , 2 nd , 3rd quarter (7/2/2001) ^b
Bis(2-ethylhexyl)phthalate	3rd quarter (10/20/2004) ^b	Did not exceed SL	Did not exceed SL

^a Ammonia was also detected in the method blank sample. See **Appendix F**.

^b Date of original letter report to the CVRWQCB.

Because sporadic detections of ammonia had occurred in ground water samples collected from up gradient well W-817-01 and from the three down gradient wells since 2001, LLNL had proposed a new SL of 0.080 mg/L for the down gradient monitor wells in 2002 (Brown 2002). The Regional Board has not yet acted to incorporate the SLs LLNL proposed in 2002. Concentrations of ammonia have remained below that proposed SL, except for occasional spikes.

Concentrations of bicarbonate alkalinity have been observed sporadically above the SL of 277 mg/L in down gradient monitor well W-817-04 since the second quarter of 2001. The concentrations of bicarbonate alkalinity are consistent with the SL that LLNL proposed in 2002 (Brown 2002) and remain below that SL.

Sporadic detections of the plasticizer compound bis(2-ethylhexyl)phthalate have occurred since 2000. Since the compound is a common laboratory contaminant, most of the detections have been accompanied by detections in method blank samples, and sometimes, in the ground water samples from the up gradient monitor well W-817-01. In the third quarter, bis(2-ethylhexyl)phthalate was detected in the ground water sample from the up gradient monitor well W-817-01, and is unlikely to have originated from the surface impoundments.

Monitoring data indicated compliance with the limits for the ground water and wastewater at the sewage evaporation and percolation ponds. None of the permitted mechanical equipment percolation pits overflowed during 2004.

1.0 Introduction

This report satisfies the Site 300 Experimental Test Site (Site 300) 2004 fourth quarter and annual monitoring and reporting requirements of the Central Valley Regional Water Quality Control Board's (CVRWQCB's) Waste Discharge Requirements 96-248 (the Permit). It details the results of compliance monitoring networks in the Explosives Process Area and the General Services Area and visual observations at a third percolation pit system at Site 300.

The High Explosive Process Area compliance network analyzes samples of ground water beneath, and process wastewater influent discharged into, two connected Class II surface impoundments where the process wastewater is evaporated. The General Services Area network analyzes samples of ground water beneath, and wastewater discharged into, the sewage evaporation and percolation ponds (sewage ponds) where sanitary waste is treated. The percolation pit network entails visual monitoring of five percolation pits that receive mechanical equipment wastewater.

Site 300, operated by LLNL, is located in the Altamont Hills approximately 13 kilometers (8 miles) southwest of the city of Tracy, California. **Figure 1** shows the locations of the surface impoundments within the Explosives Process Area and of the sewage ponds in the General Services Area of Site 300.

2.0 Class II Surface Water Impoundments

2.1 *Compliance Monitoring Program*

The Monitoring and Reporting Program in the Permit as modified in 1998 (MRP 96-248, Revision 1) specifies the required environmental monitoring for operation of the surface impoundments (Cohen 1998). These specifications include monitoring of process wastewater discharges to the surface impoundments and leak detection systems.

Process wastewater discharged to the surface impoundments is monitored for constituents found (or likely to be found) in materials used in operations conducted at buildings discharging to the surface impoundments. The monitoring program includes collecting and analyzing samples from: photographic process rinsewater from Buildings 801, 823, and 851 (**Tables A-1.1, A-1.2, and A-1.3**); Chemistry wastewater from Buildings 825, 826, and the Building 827 Complex (827A, 827C/D, and 827E) (**Tables A-2.1 through A-2.4**); and Explosives Process wastewater from Buildings 806/807, 809, and 817 (**Tables A-3.1, and A-3.2**). Discharges to the surface impoundments from Buildings 801 and 851 were discontinued after the first quarter of 2004; photographic rinsewater from those processes is now evaporated.

Leak detection system monitoring includes monitoring of the leachate collection and removal systems (LCRSs) and ground water. LCRSs installed between the clay liners of the surface impoundments are inspected weekly for the presence of moisture that might indicate a leak in the HDPE liner. Ground water samples are collected quarterly from monitor wells located up gradient and down gradient of the surface impoundments (**Figure 2**).

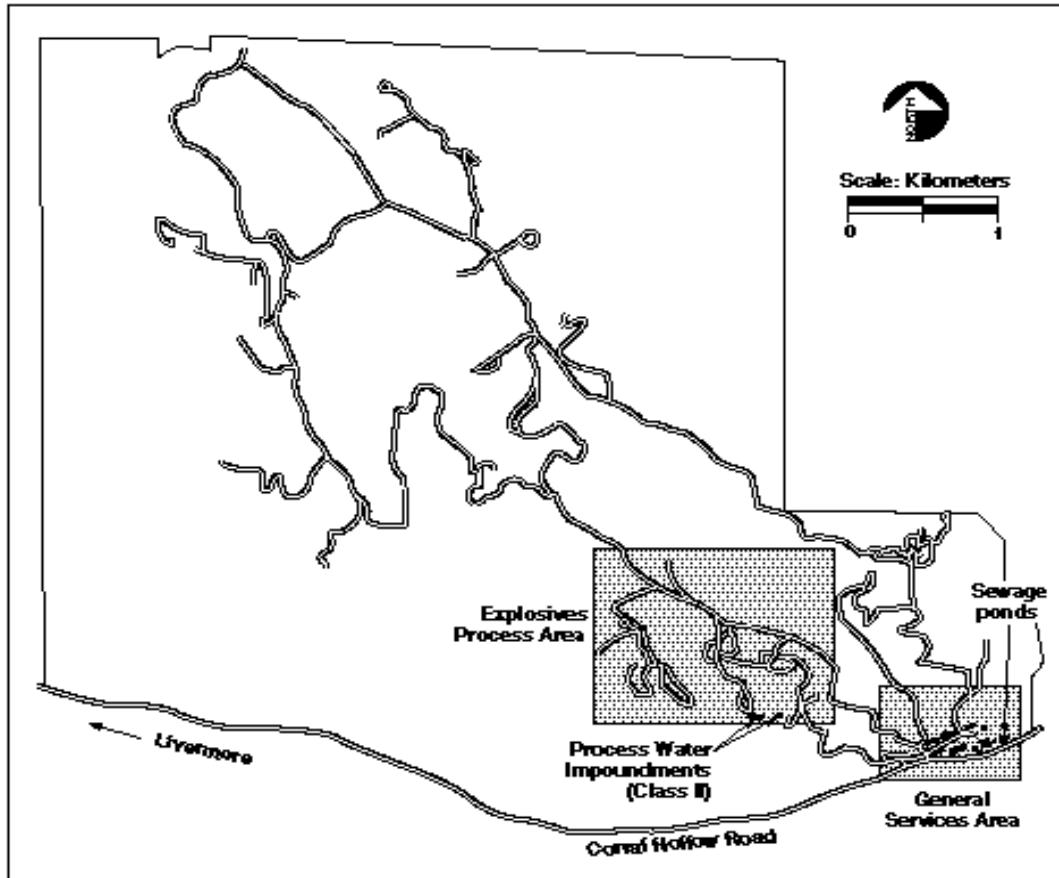

Figure 1. Location of Class II surface water impoundments and sewage evaporation and percolation ponds.

Ground water analytical results are compared with statistical test limits (SLs) to identify statistical evidence of a release of chemicals into the ground water from the surface impoundments.

The four ground water monitor wells are screened in the Tertiary Age, Neroly Formation Upper Blue Sandstone ($Tnbs_2$). The direction of ground water flow is approximately southeasterly. Monitor well W-817-01 is hydrologically up gradient of the surface impoundments, and monitor wells W-817-02, W-817-03, and W-817-04 are down gradient. LLNL collects ground water samples quarterly from these monitor wells and analyzes them for the COCs specified in MRP 96-248, Revision 1 (Cohen 1998).

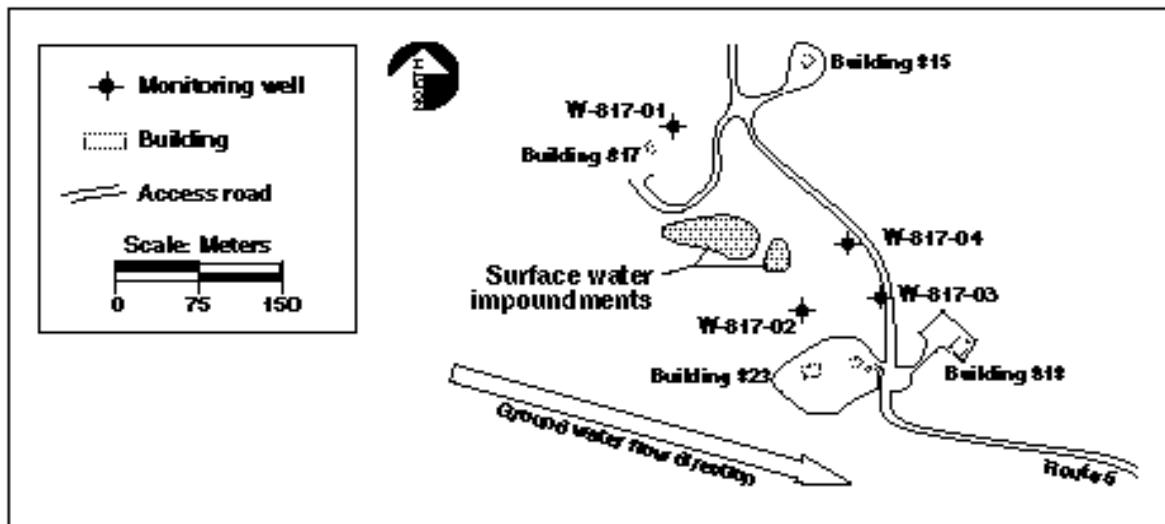

Figure 2. Site 300 Explosives Process Area ground water compliance monitoring locations.

2.2 Process Wastewater Monitoring Network

Data discussed in this section are provided in tabular form in **Appendix A (Tables A-1.1 through A-3.2)** for all 2004 data. A discussion of the process wastewater quality assurance/quality control (QA/QC) data is provided in **Appendix F** along with the associated field/method blank QA/QC data tables for the fourth quarter data (**Tables F-1.1 and F-1.2**).

2.2.1 Photographic Process Rinsewater Discharges

LLNL samples all discharges from photographic process rinsewater retention tanks at Buildings 801 and 851. Once samples are collected, the tank contents are immediately discharged to the surface impoundments. Analytical results are used to confirm that the discharges are consistent with the effluent limits specified in the Permit. Photographic process rinsewater from the Building 823 retention tank discharges automatically to the surface impoundments. Because of pump problems in the past, LLNL has switched to manual operation of the pump. This waste stream is sampled once each quarter to verify that discharges are consistent with the effluent limits specified in the Permit.

All discharges into the Class II surface impoundments were in compliance with the effluent limits during 2004. Metals concentrations in all process rinsewater discharges sampled from retention tanks were in compliance with the Permit's effluent limits during 2004. Historical data for the COCs are plotted in **Appendix A**, and the 2004 analytical results are tabulated in **Tables A-1.1, A-1.2, and A-1.3**.

During 2004, one discharge from Building 801 was sampled in the first quarter (**Table A-1.1**); each of four discharges from Building 823 were sampled in the first, second, third, and fourth quarters (**Table A-1.2**); and one discharge from Building 851 was sampled in the first quarter (**Table A-1.3**).

2.2.2 Chemistry Area Wastewater Discharges

Process wastewater generated from the Chemistry Area (Buildings 825, 826, and the Building 827 Complex) is held in retention tanks until evaluation of the analytical results from the samples collected indicates compliance with the Permit's effluent limits. Data are reported for the quarter when the discharge to the surface impoundments occurs, although wastewater samples may actually be collected in an earlier quarter.

Constituent concentrations in all process wastewater discharges that occurred during 2004 from the Building 827 Complex were in compliance with the effluent limits. No discharges occurred from the retention tanks at Buildings 825, 826, or 827A during the year. Analytical results for the Chemistry Area wastewater samples including COCs and additional analytes are presented in **Tables A-2.1 through A-2.4**. Historical data plots are included in **Appendix A**.

2.2.3 Explosives Process Area Wastewater Discharges

Wastewater generated from the Explosives Process Area (Buildings 806/807, 809, and 817) is sampled annually in accordance with MRP 96-248, Revision 1 (Cohen 1998).

The concentrations of COCs in process wastewater discharges sampled during 2004 from the Explosives Process Area were in compliance with the effluent limits. Process discharges associated with Buildings 806/807 were sampled once during the third quarter, and discharges associated with Building 817 were also sampled once during the third quarter. There were no discharges associated with Building 809; there have been no processes operating at Building 809 since construction activities began there in May 2001. Although construction has been completed, Building 809 will be offline until the final certification for the new isostatic press and ovens is complete. Annual analytical results of Explosives Process Area wastewater discharge samples are presented in **Tables A-3.1 and A-3.2**. Historical data plots are included in **Appendix A**.

2.3 Leak Detection Monitoring Network

On October 13, a split in the HDPE liner of the upper surface impoundment was discovered. The split was approximately 6 to 8 inches long and more than three feet above the present water line. Several other weak places, or striations, in the liner were noted at the same time. Repairs to all of those locations were completed November 30, 2004.

2.3.1 Leachate Collection and Removal Systems Monitoring

The two LCRSs were monitored weekly for the presence of liquids that would indicate a leak in a surface impoundment liner. No liquid was discovered in this system during 2004.

2.3.2 Ground Water Monitoring

In 2004, three COCs (ammonia in samples from well W-817-03 during the fourth quarter; bicarbonate alkalinity in samples from well W-817-04 during the first, second, and third quarters; and bis(2-ethylhexyl)phthalate in samples from well W-817-02 during the third quarter) exceeded the respective SLs. Although concentrations exceeding the SLs were

confirmed by at least one retest sample from each well, LLNL does not believe these elevated concentrations of any COC (**Table B-1.1**) originated from the surface impoundments.

Table B-1.2 lists all ground water analytical results, including retest sample results, for the fourth quarter of 2004 for COCs under MRP 96-248, Revision 1 (Cohen 1998). Analytical results from other parameters analyzed in water samples from these wells, which are not required by MRP 96-248, Revision 1, but are part of the analytical laboratory suites, are listed in **Table B-2.1**. **Appendix E** provides a brief description of all statistical methods used to evaluate compliance with the limits established in MRP 96-248, Revision 1 (Cohen 1998). A discussion of the fourth quarter ground water QA/QC data is provided in **Appendix F**, along with the field QA/QC data tables (**Tables F-2.1** and **F-2.2**).

The concentrations of ammonia analyzed in ground water samples collected on October 29 and November 1, 2004, were 0.05 mg/L from down gradient well W-817-02, 0.06 mg/L from down gradient well W-817-03, and 0.07 mg/L from down gradient well W-817-04. All of these concentrations exceeded the SL of 0.02 mg/L (**Tables B-1.1** and **B-1.2**). This exceedance was confirmed by results of the retest samples collected from well W-817-03 only on December 2, 2004, and the statistically significant evidence was reported to the CVRWQCB (Raber 2005). No concentration of ammonia analyzed in any of those wells exceeded the SL of 0.080 mg/L proposed by LLNL in 2002 (Brown 2002). See also **Table F-2.1** and **Appendix F** for a discussion of ammonia detected in the field blank sample and how that might bias these results.

Concentrations of bicarbonate alkalinity were confirmed as exceeding the current SL of 277 mg/L in samples collected from down gradient well W-817-04 during first, second, and third quarter monitoring (**Table B-1.1**) and were previously reported to the CVRWQCB at the end of the second quarter of 2001 (Raber 2001). Although the concentrations of bicarbonates from well W-817-04 exceed the current SL, they remain lower than the SL of 305 mg/L that LLNL proposed for that well in 2002 (Brown 2002).

Concentrations of the plasticizer compound bis(2-ethylhexyl)phthalate in ground water samples collected from down gradient well W-817-02 in the third quarter were confirmed as exceeding the SL of 5 µg/L. Although this statistical exceedance was reported to the CVRWQCB (Raber 2004) according to the Permit, LLNL does not believe this compound originated from the surface impoundments. This common laboratory contaminant was also detected, at an estimated concentration <5 µg/L, in the up gradient well W-817-01 in the third quarter (**Table B-1.1** and **Brown 2004**).

The energetic compound pentaerythritol tetranitrate (PETN) was detected the first time ever in ground water samples collected from down gradient monitor well W-817-02 in the second and third quarters (2.69 µg/L and 15.4 µg/L, respectively). Although this statistical exceedance was reported to the CVRWQCB (Raber 2004) according to the Permit, these statistical exceedances were not confirmed by retest samples. Likewise, concentrations of the energetic compounds hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (RDX) and 4-amino-2,6-dinitrotoluene exceeded the SLs in samples from one or more

down gradient monitor wells during the third quarter and were reported to the CVRWQCB (Raber 2004), but the concentrations of these compounds were not confirmed as exceeding their SLs.

Plots of all COC data over time and tabular annual summaries of the ground water analytical data are included in **Appendix B**.

3.0 Sewage Evaporation and Percolation Ponds

3.1 *Compliance Monitoring Program*

Monitoring at the sewage evaporation pond (evaporation pond) and the sewage percolation pond (percolation pond) (**Figure 3**) is also specified in the MRP 96-248, Revision 1 (Cohen 1998). Applicable reporting requirements are detailed in the Permit (CVRWQCB 1996).

Quarterly samples of wastewater flowing into the evaporation pond are collected for analysis from a location west of the pond (sampling location ISWP in **Figure 3**). ISWP is a manhole that captures all waste streams before they flow into the pond. The samples are analyzed for electrical conductivity (EC), pH, and biochemical oxygen demand (BOD).

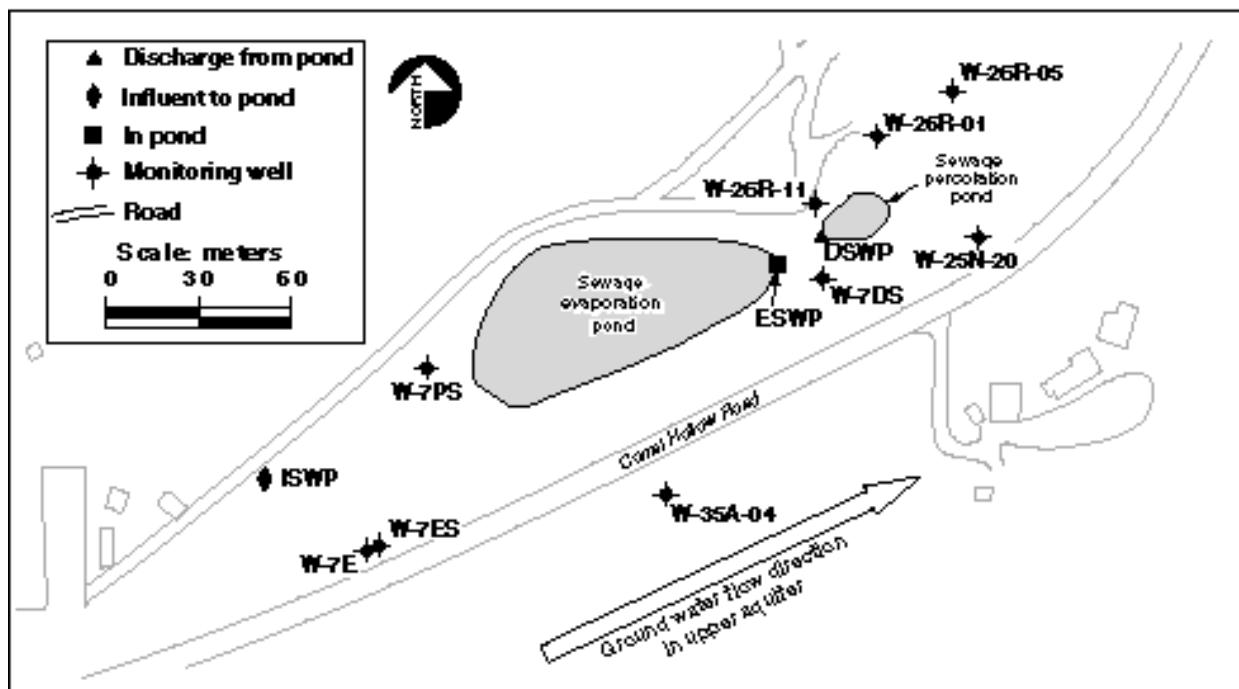

Quarterly wastewater samples are collected from the evaporation pond (sampling location ESWP) and analyzed for pH, EC, and dissolved oxygen (DO). Observations of the pond are made at least monthly for freeboard, color, odor, and levee condition. Any discharge from the evaporation pond to the percolation pond (sampling location DSWP) is sampled and analyzed for BOD, EC, total and fecal coliform, and pH.

Leak detection monitoring at the sewage ponds is accomplished by monitoring the shallow ground water, including the regional aquifer (Tnbs₁) beneath and adjacent to the ponds. Ground water monitoring includes semiannual sampling and analysis of the collected samples. **Table 2** lists each monitor well; and whether it is up gradient, down gradient, or cross gradient of the sewage ponds; and the geological interval(s) over which it is screened. **Figure 3** shows the location of each of the wells.

Table 2. Monitor well location relative to sewage ponds and aquifer monitored.

Monitor well	Location	Screening interval
W-7E	Up gradient	Tnsc ₁ /Tnbs ₁
W-7ES	Up gradient	Qal/Tnsc ₁
W-7PS	Up gradient	Qal
W-35A-04	Cross gradient	Qal
W-26R-01	Down gradient	Tnbs ₁
W-26R-11	Down gradient	Qal
W-26R-05	Down gradient	Qal/Tnbs ₁
W-25N-20	Down gradient	Qal/Tnbs ₁
W-7DS	Down gradient	Qal/Tnbs ₁

Note: Tnbs₁ is the regional aquifer.

**Figure 3.** Site 300 sewage pond ground water and surface water compliance monitoring locations

3.2 Wastewater Monitoring

All required wastewater monitoring parameters for the sewage ponds were in compliance with the Permit's provisions and specifications throughout 2004. Continuous discharge occurred during the first quarter (**Table C-4**) from the evaporation pond to the percolation pond (Brown 2004a). Historical plots and tabular summaries of the 2004 data are included in **Appendix C**.

3.3 Ground Water Monitoring

All required monitoring parameters for the sewage pond ground water network were in compliance with specified ground water receiving limits throughout 2004. Semiannual ground water samples were collected and analyzed during the first and third quarters of

2004. Historical data plots and tabular annual summaries of the analytical data are included in **Appendix D**.

4.0 Percolation Pits

MRP 96-248, Revision 1, requires monthly inspections of the percolation pits at Buildings 806A, 827A, 827C, 827D, and 827E. Sampling and analysis for metals is required whenever an overflow occurs.

During 2004, the percolation pits at Buildings 806A, 827A, 827C, 827D, and 827E operated normally, and no overflows occurred. The percolation pits at both Buildings 827C and 827D contained standing water throughout the fourth quarter.

Appendix A

Annual Summary Plots and Tables of Surface Impoundments Process Water Monitoring Data

Appendix A

This appendix contains graphical and tabular summaries of the 2004 surface water impoundments influent monitoring. The monitoring requirements of WDR 96-248 began in the fourth quarter of 1996.

Wastewater influent monitoring includes photographic process water from Buildings 801, 823, and 851; the Chemistry Area (Buildings 825, 826, and 827 Complex); and discharges from the Explosives Process Area (Buildings 806, 807, 809, and 817).

Retention tank designations for the photographic process and Chemistry Areas are as follows: 801-R3O1 (old), 801-R3O2 (new), 823-R1U1, 851-R1A1 (photographic process area); and 825-R1A1, 826-R1A1, 827A-R1A1, 827C-R1A1, and 827A-R2A1 (Chemistry Area). Process discharges from the Explosives Process Area are generated from Buildings 806/807 and 817 and are designated as B806/807 and B817, respectively. The plots contain all monitoring data available since LLNL began storing sample results from these retention tanks in 1992. There are no 2004 data for B809 because there have been no operations there since May 2001.

The plots display the pH parameter and concentrations of trace metals, volatile organic compounds, and semi-volatile organic compounds in wastewater influent to the surface water impoundments. The plots begin with the retention tank associated with the lowest building number for each detected analyte always plotted first. Only analytes detected in each retention tank are plotted.

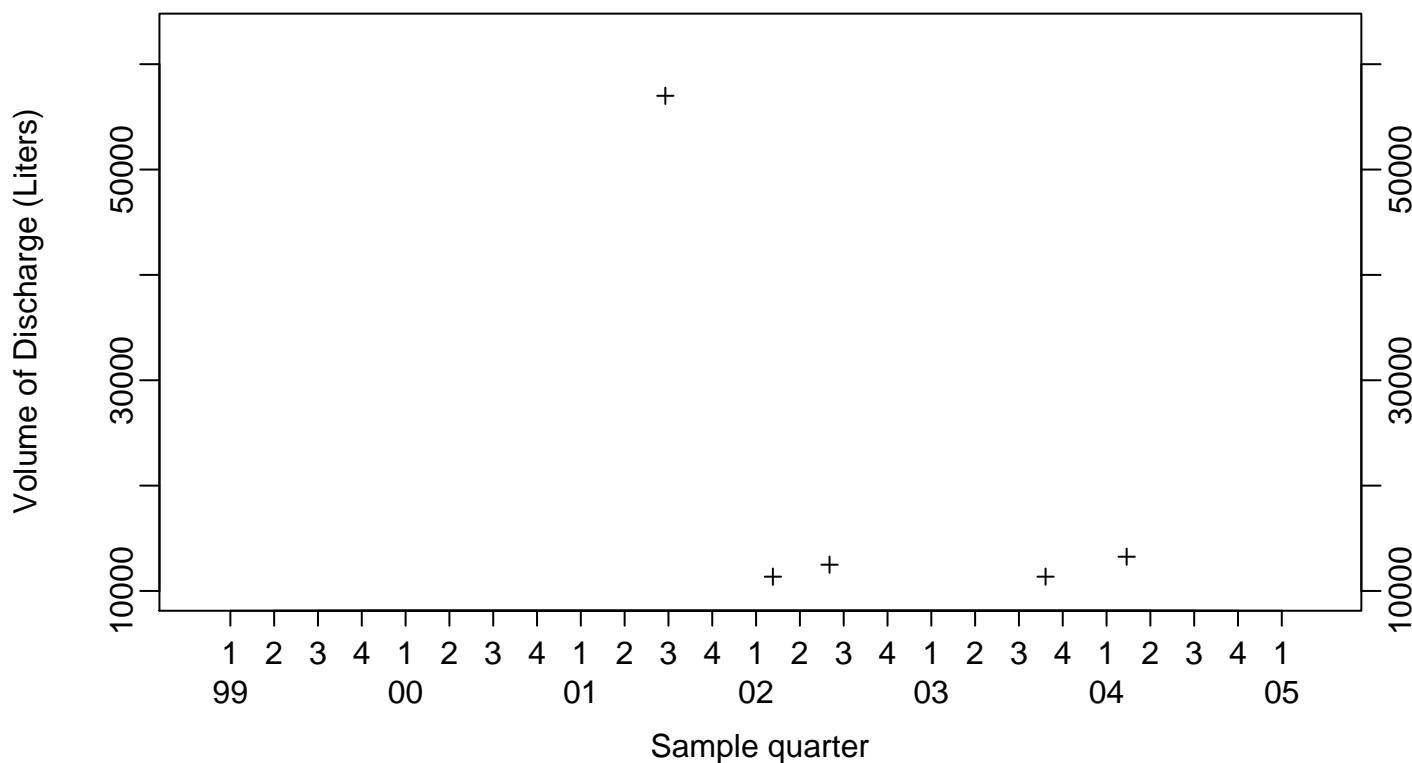

Each two-dimensional graph plots concentration on the vertical axis versus time (years divided into four quarterly sampling periods) on the horizontal axis. Units of measure are given on the vertical axis label and in the header at the top of each page. Values above the analytical reporting limit for each analyte are plotted as solid diamonds, values below the reporting limit are plotted as open inverted triangles, and the estimated values between the reporting limit and method detection limit are plotted as crosses.

Appendix B

Annual Summary Plots and Tables of Surface Impoundments Ground Water Monitoring Data

Appendix B

This appendix contains graphical and tabular summaries of ground water monitoring data from the surface impoundments ground water monitoring network. The constituents of concern for WDR 96-248 are shown graphically, and the tables at the end of this appendix list all 2004 ground water data. The data plots contain all monitoring data available since 1999.

These plots display the field parameter of ground water elevation, followed by volatile organic compounds (VOCs), trace metals, photographic chemicals (cresols), minerals and nutrients, energetic compounds, and finally, semi-volatile organic compounds (SVOCs). The upgradient (background) monitoring well W-817-01 is always plotted first for each analyte.

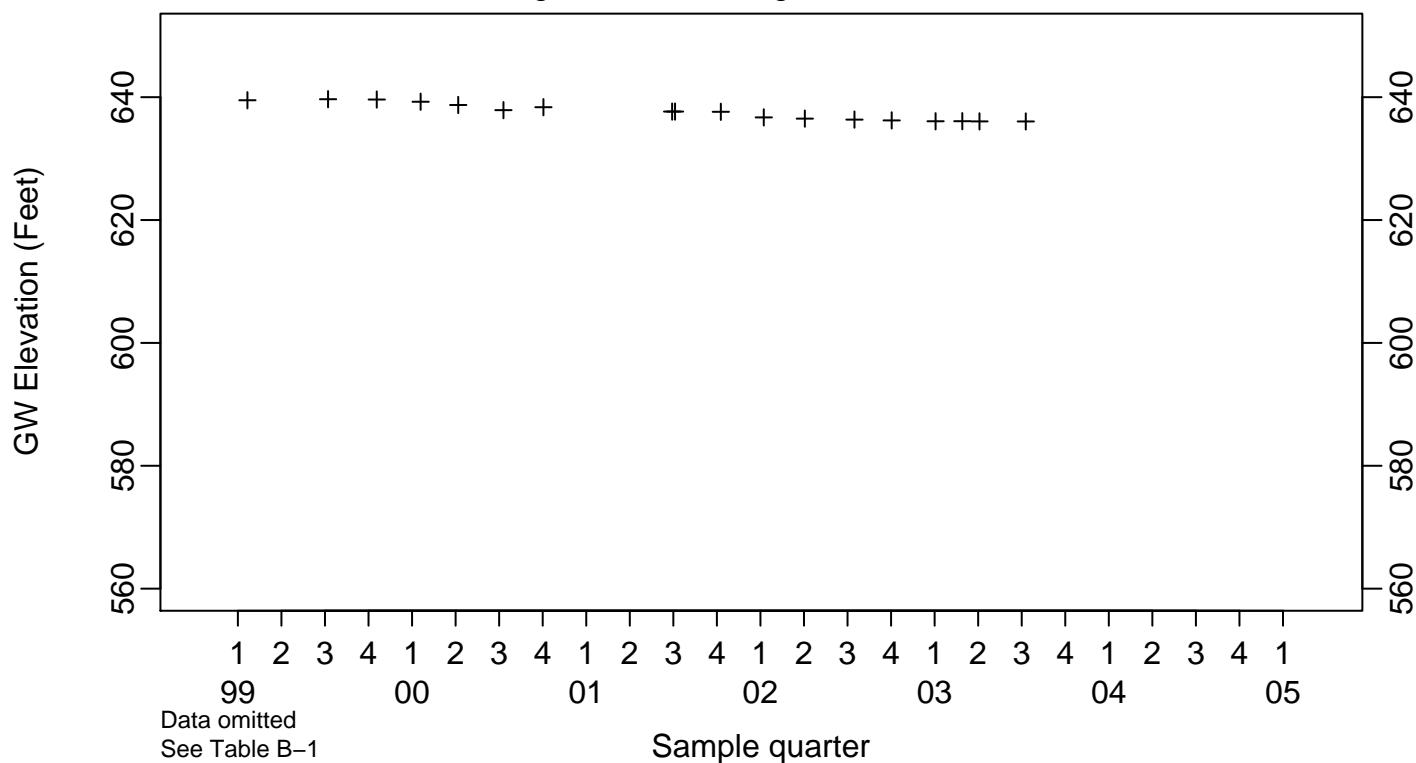

Each two-dimensional graph shows concentration plotted on the vertical axis versus time (years divided into four quarterly sampling periods) on the horizontal axis. Units of measure are given on the vertical axis label and in the header at the top of each page. Values above the analytical reporting limit for each analyte are plotted as solid diamonds, values below the reporting limit are plotted as open inverted triangles, and estimated values between the reporting limit and the method detection limit are plotted as crosses. The current statistical limits (SLs) for constituents of concern specified in WDR 96-248 are shown as horizontal dashed lines on the graph.

^a Statistical limit as listed in MRP 96-248, Table 5, modified by CVRWQCB letter (Cohen 1998) dated September 25, 1998.

^b NA = Not applicable.

^c Results followed by an "est" have estimated concentrations between the MDL and the reporting limit for that analyte.

^d The exceedance of the SL was confirmed by retest sample results.

^e The exceedance of the SL was not confirmed by retest sample results.

^t NS = Not sampled. Water from well W-817-01 was not analyzed for energetic materials, except for TATB.

^a MDL = Method detection limit.^b Statistical limit as listed in MRP 96-248, Table 5, modified by CVRWQCB letter (Cohen 1998) dated September 25, 1998.^c NA = Not applicable.^d Results followed by an "est" have estimated concentrations between the MDL and the reporting limit for that analyte.^e These concentrations of ammonia may be biased high because ammonia was detected in the field blank sample at a concentration of 0.03 mg/L. See also **Appendix F** and **Table F-2.1**.^f None of the retest samples collected and analyzed for ammonia from wells W-817-02 and W-817-04 exceeded the SL of 0.02 mg/L.^g The retest sample collected from well W-817-03 on Dec. 2, 2004, and analyzed for ammonia exceeded the SL.^h NS = Not sampled and analyzed for this COC.

Appendix C

Annual Summary Plots and Tables of Sewage Evaporation and Percolation Ponds Wastewater Monitoring Data

Appendix C

This appendix contains graphical and tabular summaries of the 2004 sewage evaporation and percolation ponds wastewater monitoring data. The monitoring requirements of WDR 96-248 began in the fourth quarter of 1996.

Wastewater influent monitoring at location ISWP consists of pH, electrical conductivity (EC), and biochemical oxygen demand (BOD). Routine wastewater monitoring at location ESWP consists of pH, EC, and dissolved oxygen (DO); BOD was also analyzed only during the first quarter of 2004. A continuous discharge from the sewage evaporation pond into the percolation pond at location DSWP began in December 2003 and continued into the first quarter of 2004. Samples of the continuous discharge were collected on January 27 and February 25, 2004, and analyzed for pH, EC, BOD, nitrate, and fecal and total coliform bacteria.

Each two-dimensional graph plots concentration on the vertical axis versus time (years divided into four quarterly sampling periods) on the horizontal axis. Units of measure are given on the vertical axis label and in the header at the top of each page. Values above the analytical reporting limit for each analyte are plotted as solid diamonds, and values below the analytical reporting limit are plotted as open inverted triangles. Data determined not to be valid are not plotted.

Tabular summaries of the observations are contained in **Tables C-1 to C-4**, starting on page C-18.

Appendix D

Annual Summary Plots and Tables of Sewage Evaporation and Percolation Ponds Ground Water Monitoring Data

Appendix D

This appendix contains graphical and tabular summaries of ground water monitoring data from the sewage ponds ground water network. These plots contain all monitoring data available since LLNL began sampling from upgradient ground water monitoring wells W-7E, W-7ES, and W-7PS; from cross-gradient ground water monitoring well W-35A-04; and from downgradient ground water monitoring wells W-26R-01, W-26R-11, W-26R-05, W-25N-20, and W-7DS in 1987.

The plots display field parameters of ground water elevation, pH, electrical conductivity (EC), total coliform bacteria, fecal coliform bacteria, and finally nitrate (as NO₃). The upgradient (background) monitoring wells W-7E, W-7ES, and W-7PS are always plotted first for each analyte.

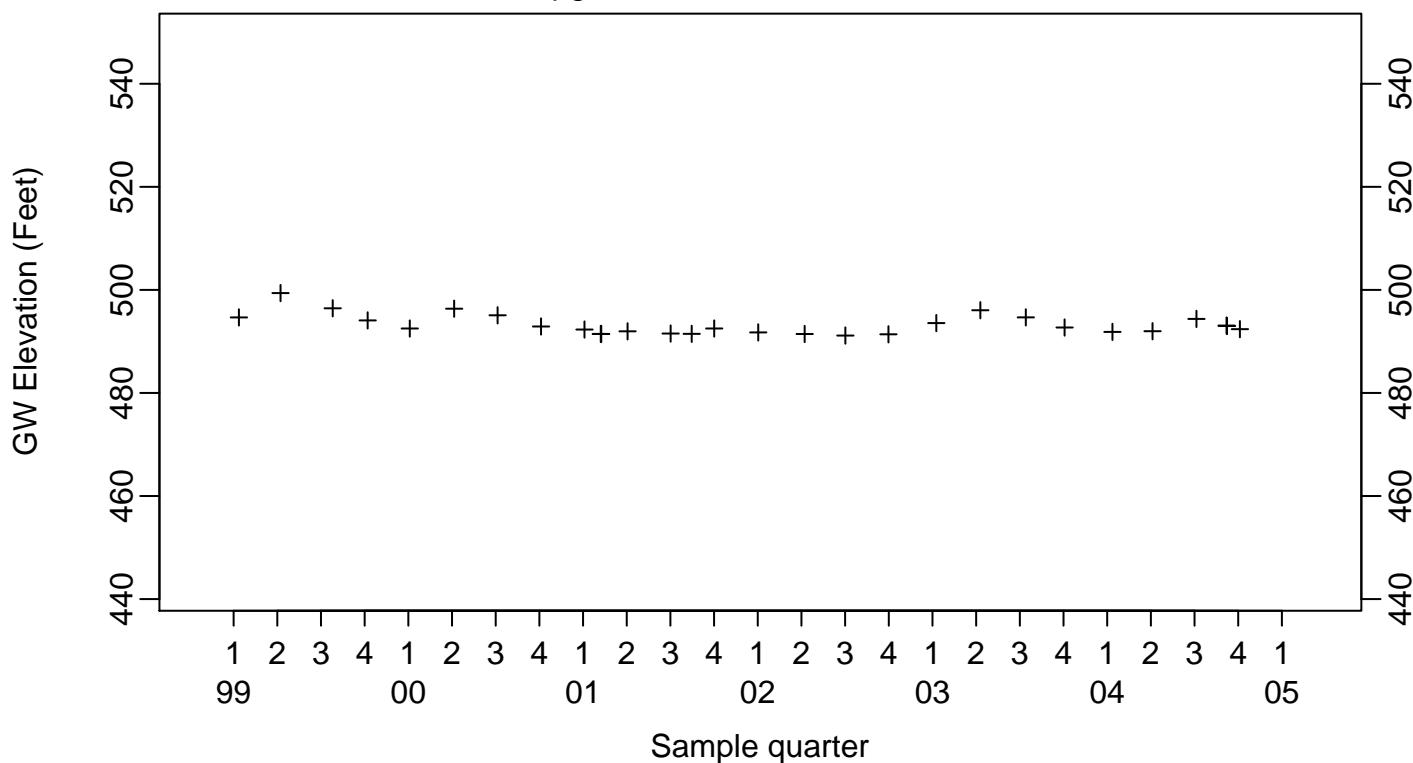

Each two-dimensional graph shows concentration plotted on the vertical axis versus time (years divided into four quarterly sampling periods) on the horizontal axis. Units of measure are given on the vertical axis label and in the header at the top of each page. Values above the analytical reporting limit for each analyte are plotted as solid diamonds, and values below the reporting limit are plotted as open inverted triangles.

Appendix E

Statistical Analyses for Ground Water Data

Appendix E

Statistical Analyses

Statistical Methods

Statistical methods are used to detect increases in concentrations of COCs that may indicate releases of COCs to ground water. The CVRWQCB *Standard Provisions* (1993) accompanying WDR 96-248 require the use of statistical methods from the *California Code of Regulations* (CCR), Title 23, Chapter 3, Subchapter 15.

Two statistical methods, prediction intervals and control charts, are used to generate concentration limits and statistical test limits (SLs) for COCs in ground water samples from the surface impoundments monitoring network. Both methods are sensitive in indicating COC concentration increases, and both methods require only one sample per monitoring well for each COC per quarter. Prediction intervals are used when COC concentrations are statistically similar in each of the three down gradient wells to those in the upgradient well, W-817-01. The method of control charts is used when COC concentrations in the downgradient wells are statistically different from those in the upgradient well. A COC is considered to have exceeded its concentration limit when a single ground water analytical result exceeds its SL and either of two subsequent re-tests also exceeds the SL (**Table B-1.2**). **Table E-1** provides a summary and status of the reported COCs that have shown statistically significant evidence of release.

Table E-1. Reported COCs showing statistically significant evidence of release.

Constituent	Date first reported	Monitor wells	Status of investigation
Zinc	1/9/97	W-817-02, W-817-03	In progress, CERCLA
Chloride	2/7/97	W-817-03	Complete
Arsenic	4/14/97	W-817-02, W-817-03, W-817-04	In progress, under CERCLA

Appendix F

Fourth Quarter Quality Assurance/Quality Control Monitoring Data Discussion, Surface Impoundments Monitoring Networks

Appendix F

Quality Assurance/Quality Control

1.0 Quality Assurance (QA) Program

To ensure data quality, LLNL utilizes an extensive written set of protocols and procedures that covers all aspects of ground water and surface water sampling, sample tracking, and environmental data management. The *LLNL Livermore Site and Site 300 Environmental Restoration Project Standard Operating Procedures* (Goodrich and Depue, 2004), and the *Environmental Monitoring Plan* (Althouse *et al.*, 2002) form the set of written instructions to be followed. Observing these protocols prevents inadvertent sample contamination and maintains sample integrity from the sampling location to the analytical laboratories. Data management procedures ensure that all laboratory measurements are received, accurately recorded, and properly stored in a computer database for easy and fast retrieval. Hard copies of the data are also archived. All sample analyses for the surface water impoundments meet the reporting criteria delineated in the Permit as modified by Wendy Cohen of CVRWQCB on September 25, 1998 (Cohen, 1998) (**Tables F-1.1 through F-2.2**).

1.1 Field Procedures

As a part of the QA program, data quality for the sampling activities during each quarter is assessed by the following method: field blanks use analyte-free water for the analyses of organic compounds and high-performance liquid chromatography (HPLC)-grade water for all other required analyses. Field blanks, which are prepared at monitor wells and wastewater sample locations chosen at random, are analyzed for parameters identical to those for the routine samples. Field blank data are reviewed by analysts to determine whether contamination has been introduced into the samples as a result of field conditions or sample handling procedures.

1.1.1 Process Wastewater Influent

Field QA procedures include adherence to the *Environmental Monitoring Plan* (Althouse *et al.*, 2002). These include approved procedures for: sample preparation, handling, preservation, custody, and equipment decontamination procedures. Field activities are recorded on field tracking forms and/or in logbooks, and sample tracking is maintained through the chain-of-custody process. Field QA protocols include the preparation of at least 10 percent duplicate or collocated samples. The purpose of field duplicates is to verify the precision and comparability of the sampling activity. Additionally, temperature blanks are included in each shipping container of samples to verify that the temperature is maintained at $4^{\circ} \pm 2^{\circ}$ Celsius until receipt at the analytical laboratories.

1.1.2 Ground Water Monitoring

Field QA procedures include adherence to the sampling and analysis protocols of the *LLNL Livermore Site and Site 300 Environmental Restoration Project Standard Operating Procedures* (Goodrich and Depue, 2004). These include approved procedures for: sample collection, preparation, handling, preservation, custody, and equipment decontamination procedures. Field activities are recorded on field sampling sheets and/or in logbooks, and sample tracking is maintained through the chain-of-custody process. Field QA protocols include the preparation of at least 10 percent duplicate or collocated samples. The purpose of field collocated samples is to verify the precision of the sampling and analysis activities. Significant differences between duplicate samples (which should have identical results within the margin of sampling and analytical errors) are investigated by the responsible analysts, in collaboration with an LLNL quality control chemist. Field blanks are prepared at random locations to assess sample hygiene and handling practices.

1.2 Analytical Laboratories

LLNL contracts with several outside analytical laboratories. They provide routine analytical services that meet the requirements of LLNL's QA documents, as well as the requirements cited in the Permit. Analytical laboratories used by LLNL and each laboratory's responsible person are:

- BC Laboratories, Inc.
4100 Atlas Court
Bakersfield, CA 93308
Laboratory Responsible Person: Chrissy Herndon
- General Engineering Laboratories
P.O. Box 30712
2040 Savage Road
Charleston, SC 29414
Laboratory Responsible Person: Cheryl Jones
- Sequoia
885 Jarvis Drive
Morgan Hill, CA 95037
Laboratory Responsible Person: Lisa Race

These laboratories perform extensive quality control analyses including: method blank analyses, analyses of laboratory control samples (LCS), matrix spike (MS), and matrix spike duplicates (MSD), and analyses of surrogate samples for organic compounds. Additionally, these laboratories provide data reports of tentatively identified compounds (TICs) for volatile and semivolatile organic compounds (VOCs and SVOCs), analyzed by gas chromatography/mass spectroscopy, and provide estimated concentrations. (TICs are currently reported in the data tables of this report.) Each of these laboratories is accredited by the California Department of Health Services for the analyses

performed. Résumés of the analysts' education and qualifications are available through each laboratory.

2.0 Quality Assurance and Quality Control Results

2.1 Process Wastewater Influent

Field QA/QC data discussed in this section are contained in **Table F-1.1**.

Routine fourth quarter photographic process rinsewater samples were submitted to Sequoia and duplicate samples were submitted to BC Laboratories, Inc. for interlaboratory comparison. Metals and pH laboratory QA/QC (i.e., MS/MSD and LCS) data associated with the samples, verified per EPA Functional Guidelines for data review (U.S. Environmental Protection Agency, 1994a and 1994b), showed that all data are usable.

Representative samples were collected from the retention tank at Building 823 on November 23, 2004. Metal concentrations show the variations experienced for certain metals (such as copper, silver and zinc) between the routine and duplicate samples collected from the Building 823 retention tank. No metals were detected in the method blank above laboratory reporting limits (**Table F-1.1**).

2.2 Ground Water Monitoring

Analyte concentrations of routine and duplicate samples collected from down gradient monitor well W-817-02 are in very good agreement for the COCs detected above their respective reporting limits (**Table F-2.1**).

No COC or non-COC compounds were detected in method blank samples above laboratory reporting limits during the fourth quarter (**Tables F-2.1** and **F-2.2**). Of the COCs, only ammonia as N (0.03 mg/L) and dissolved zinc (0.0059 mg/L est.) were detected in field blank samples at concentrations that could potentially be of regulatory significance (**Table F-2.1**). Concentrations of ammonia as N in the routine fourth quarter ground water samples collected from all three down gradient wells – W-817-02, W-817-03, and W-817-04 – exceeded the current SL of 0.02 mg/L (**Tables B-1.1** and **B-1.2**). Those analytical results are likely biased high due to the detectable presence of ammonia in the field blank sample (**Table F-2.1**). Ammonia was detected in only one of the six retest samples collected from those three wells (**Table B-1.2**). The estimated concentration of 0.0059 mg/L of dissolved zinc detected in the field blank sample indicates that the concentrations detected in the ground water samples collected from all four wells might be biased high due to field contamination. However, this is not a significant issue for zinc because concentrations in the down gradient wells did not exceed any SL for zinc. Recoveries for all LCS samples and for all MS and MSD samples are within laboratory acceptance limits, so that these data meet all requirements for data accuracy as well as precision.

Laboratory QA/QC (i.e., MS/MSD and LCS) data associated with all ground water samples and evaluated per EPA Functional Guidelines for data review (U.S. Environmental Protection Agency, 1994a and 1994b), showed all parameters within acceptable ranges for data usability.

Table F-1.1 Photographic process rinsewater QA/QC results, Building 823, constituents of concern required by WDR 96-248.
